PAPER 210

TOPICS IN STATISTICAL THEORY

Attempt no more than THREE questions.

There are FOUR questions in total.

The questions carry equal weight.

SPECIAL REQUIREMENTS

None

You may not start to read the questions printed on the subsequent pages until instructed to do so by the Invigilator.
Let $X_1, X_2, \ldots, X_n$ ($n \geq 2$) be independent and identically distributed random variables with density function $f$.

Define the *univariate kernel density estimator* $\hat{f}_h$, with kernel $K$ and bandwidth $h$. Show that

$$E\{\hat{f}_h(x)\} = (K_h \ast f)(x),$$

where $(g \ast f)$ denotes the convolution between $g$ and $f$, and $K_h$ is a function which you should specify.

Let the kernel be $K(z) = 1_{\{|z| \leq 1/2\}}$. Suppose that $f$ is twice differentiable with bounded second derivative. Show that, for all $n \geq 2$, $h > 0$ and $x \in \mathbb{R}$,

$$|E\{\hat{f}_h(x)\} - f(x)| \leq \frac{h^2}{24} \sup_{z \in \mathbb{R}} |f''(z)|.
$$

Show that, for $t > 0$,

$$P\left[|\hat{f}_h(x) - E\{\hat{f}_h(x)\}| \geq t\right] \leq 2 \exp\left(-\frac{2nht^2}{t^2}\right).$$

By integrating this bound, deduce that, for all $n \geq 2$, $h > 0$ and $x \in \mathbb{R}$, we have

$$\text{Var}\{\hat{f}_h(x)\} \leq \frac{1 + \log 2}{2nh^2}.$$

Part III, Paper 210
Let $(X, Y)$ be a random pair taking values in $\mathbb{R}^d \times \{0, 1\}$. Let $\eta(x) := \mathbb{P}(Y = 1|X = x)$, and let $P_X$ denote the marginal distribution of $X$. Define the Bayes classifier $C^\text{Bayes}$ and find its risk $\mathbb{P}(C^\text{Bayes}(X) \neq Y)$.

Now let $(X_1, U_1), \ldots, (X_n, U_n)$ be independent pairs, with $X_i \sim P_X$, $U_i \sim U[0, 1]$, with $X_i$ and $U_i$ independent, for $i = 1, \ldots, n$. Let $Y_i := \mathbb{I}_{U_i \leq \eta(X_i)}$. Show that the pair $(X_1, Y_1)$ has the same joint distribution as $(X, Y)$.

For $k \in \{1, \ldots, n\}$, define the $k$-nearest neighbour classifier, denoted by $\hat{C}_n^{\text{nn}}$, with training data $(X_1, Y_1), \ldots, (X_n, Y_n)$.

Consider the case $k = 1$. Given $x \in \mathbb{R}^d$, let $Y_i' = Y_i'(x) := \mathbb{I}_{U_i \leq \eta(x)}$, and let $(X(1)(x), U(1)(x)), \ldots, (X(n)(x), U(n)(x))$ denote a reordering of the pairs $(X_1, U_1), \ldots, (X_n, U_n)$, such that

$$\|X(1)(x) - x\| \leq \|X(2)(x) - x\| \leq \ldots \leq \|X(n)(x) - x\|.$$

Let $\tilde{C}_n^{\text{nn}}$ denote the 1-nearest neighbour classifier trained with the pairs $(X_1, Y_1'), \ldots, (X_n, Y_n')$. Show that, for each $x \in \mathbb{R}^d$,

$$\mathbb{P}(\tilde{C}_n^{\text{nn}}(x) \neq C_n^{\text{nn}}(x)) = \mathbb{E}[|\eta(X(1)(x)) - \eta(x)|].$$

Write

$$L(C) := \mathbb{P}\{C(X) \neq Y|(X_1, Y_1, U_1), \ldots, (X_n, Y_n, U_n)\}.$$

Deduce that

$$\lim_{n \to \infty} \mathbb{E}\{L(\tilde{C}_n^{\text{nn}})\} = \lim_{n \to \infty} \mathbb{E}\{L(\hat{C}_n^{\text{nn}})\} = \mathbb{E}[2\eta(X)(1 - \eta(X))].$$

[You may use the fact that $\mathbb{E}[|\eta(X(1)(x)) - \eta(x)|] \to 0$ as $n \to \infty$ without proof.]

Deduce further that

$$\mathbb{P}(C^\text{Bayes}(X) \neq Y) \leq \lim_{n \to \infty} \mathbb{E}\{L(\tilde{C}_n^{\text{nn}})\} \leq 2\mathbb{P}\{C^\text{Bayes}(X) \neq Y\}.$$
Let $P, Q$ be two probability measures on a measurable space $(\mathcal{X}, \mathcal{A})$, and let $\nu$ be a $\sigma$–finite measure on $(\mathcal{X}, \mathcal{A})$. Suppose that $P$ and $Q$ are mutually absolutely continuous with respect to $\nu$, and dominated by $\nu$. Define the Kullback–Leibler $KL(P,Q)$, Total Variation $TV(P,Q)$ and Hellinger $h(P,Q)$ distances between $P$ and $Q$. Show that

$$TV(P,Q) \leq h(P,Q) \leq \sqrt{KL(P,Q)}.$$  

[Hint: You may use the fact that $\log(1 + x) \leq x$ for $x > -1$ without proof.]

State and prove Le Cam’s two points lemma.

Let $X_1, \ldots, X_n$ be an independent and identically distributed sample from $N(\mu, \sigma^2)$ where $\sigma$ is a known constant. Show that there exists $c > 0$ such that

$$\sup_{\mu \in \mathbb{R}} \mathbb{E}|\hat{\mu} - \mu| \geq \frac{c}{\sqrt{n}},$$

for any estimator $\hat{\mu}$.  

Part III, Paper 210
Consider a fixed design homoscedastic regression model

\[ Y_i = m(x_i) + \sigma \epsilon_i, \quad \text{for } i = 1, 2, \ldots, n, \]

where \( a < x_1 < \ldots < x_n < b \) and \( \epsilon_i \) are independent and identically distributed with \( \mathbb{E}(\epsilon_i) = 0 \) and \( \text{Var}(\epsilon_i) = 1 \).

Define a cubic spline on \([a, b]\) with knots at \( x_1, \ldots, x_n \). When is a cubic spline a natural cubic spline? Define the natural cubic spline interpolant to \( g = (g_1, \ldots, g_n)^T \) at \( x_1, \ldots, x_n \).

Let \( g \) denote the natural cubic spline interpolant to \( g = (g_1, \ldots, g_n)^T \) at \( x_1, \ldots, x_n \). Show that for any twice continuously differentiable function \( \tilde{g} \) on \([a, b]\) satisfying \( \tilde{g}(x_i) = g_i \), for \( i = 1, \ldots, n \), we have

\[ \int_a^b g''(x)^2 \, dx \leq \int_a^b \tilde{g}''(x)^2 \, dx, \]

with equality if and only if \( \tilde{g} = g \).

Deduce that, for each \( \lambda \in (0, \infty) \), there exists a unique minimiser \( \hat{g}_\lambda \), which you should specify, of

\[ S_\lambda(\tilde{g}) := \sum_{i=1}^n (Y_i - \tilde{g}(x_i))^2 + \lambda \int_a^b \tilde{g}''(x)^2 \, dx \]

over \( \tilde{g} \in S_2[a, b] \), the set of twice continuously differentiable functions on \([a, b]\).

[In this question you may use the fact that the natural cubic spline interpolant to \( (g_1, \ldots, g_n)^T \) at \( x_1, \ldots, x_n \) is unique, and that there exists a nonnegative definite matrix \( \Gamma \), such that \( \int_a^b g''(x)^2 \, dx = g^T \Gamma g \).]
